Project Name: NQ

For my senior design project, NQ, the goal is to aggregate the different ways we consume media and make a recommendation for the next thing to put in queue. This project is subject to several constraints, including economic, professional, and legal. Because I am working on this project alone without a source of outside funding, all costs will fall on me. This limits the scale of data I can store and the amount of computing power I have access to. For this reason, I have to spend more time ensuring that I only fetch and store relevant media, instead of getting as much data as possible. Also, I will be encountering legal constraints due to the availability of metadata for media. I can only use sources of metadata that are not subject to copyright or other legal restrictions. Because of this, I have to rely on free and open-source software where possible, as they often have licenses that allow use with documentation. Another constraint from me being a solo developer on this project is that the quality of the final product will be based only on the quality of my own work. This means I need to ensure that all code reflects the kind of work I want a current or future employer to see. By using up and coming technologies, I can potentially increase the number of jobs I can apply for, but only if the project demonstrates these skills well.
